# Monolithic Browser Design

Web Page

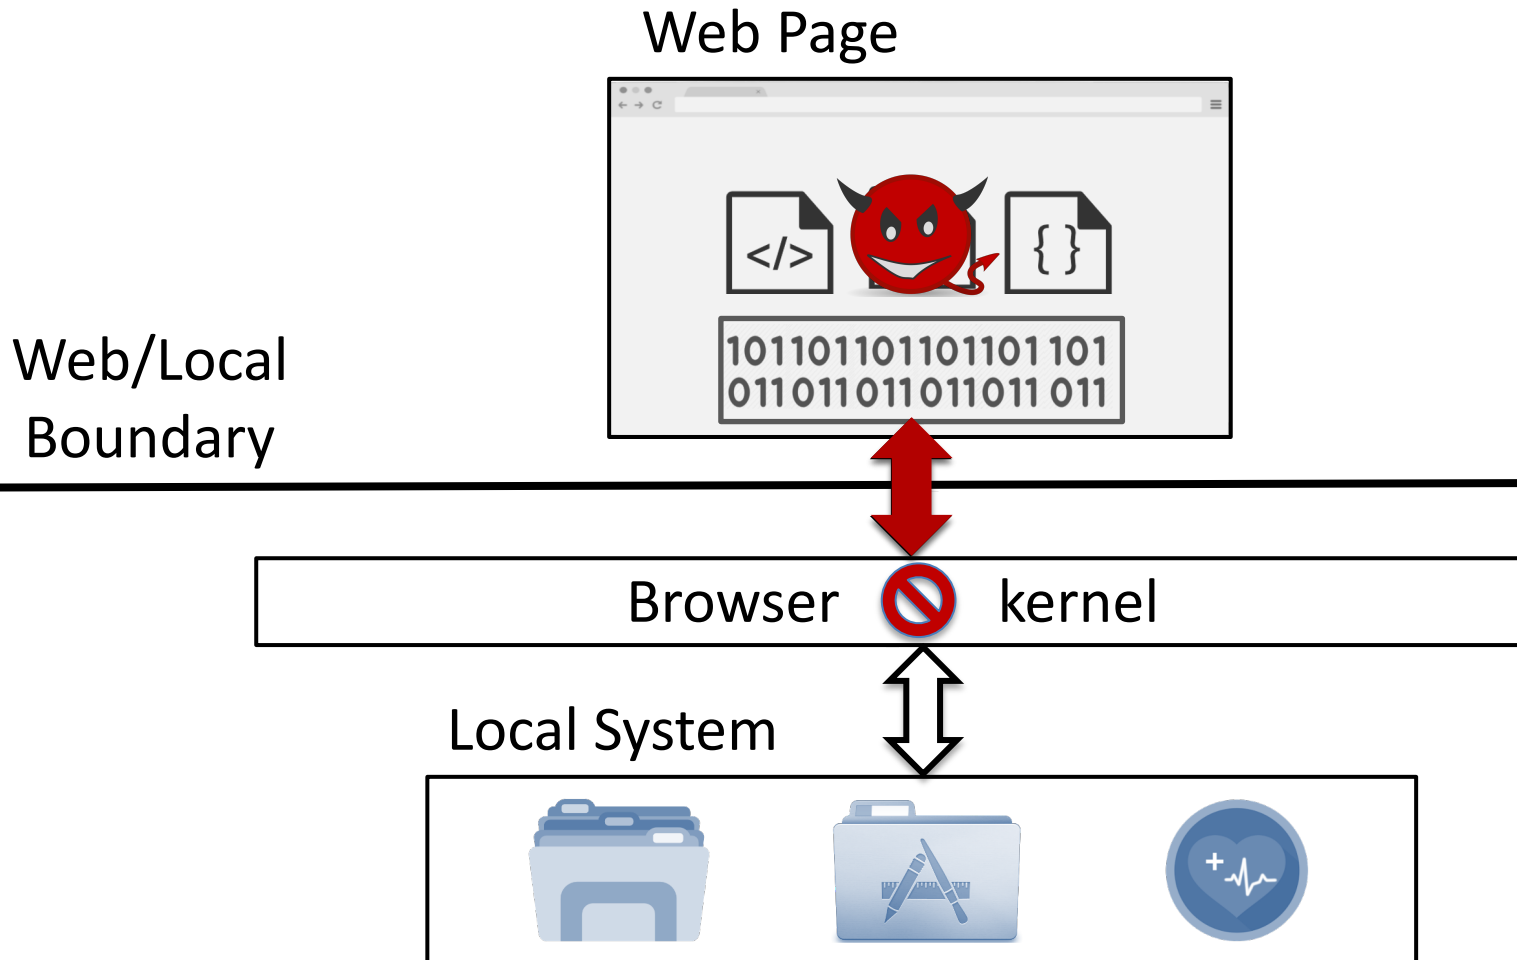

Local System

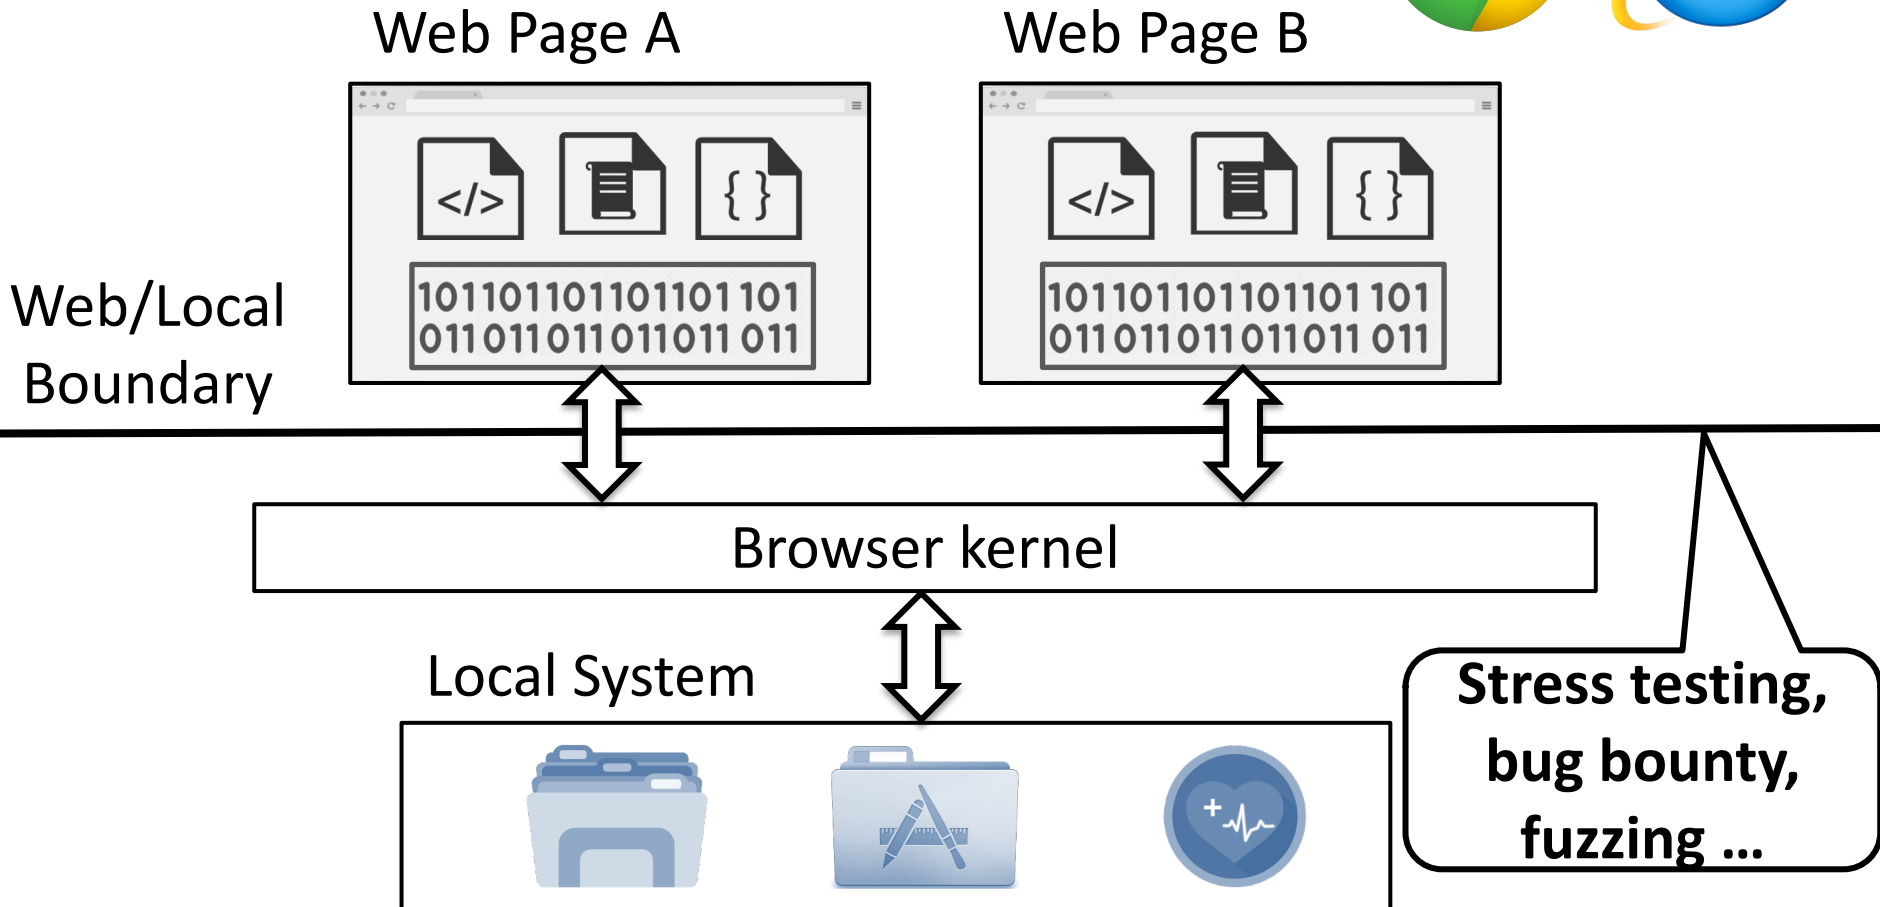

# 2<sup>nd</sup> Generation Browser: Process-based Isolation

- Process-based sandboxing – process boundary

# Is the Web/Local Boundary Sufficient?

- Used by most modern browsers

# Contributions

- The Web/Local Boundary is Fuzzy !

## **Concrete Attacks**

- Access local files, system control
- Use 1 bug in renderer process

## **Attack Details**

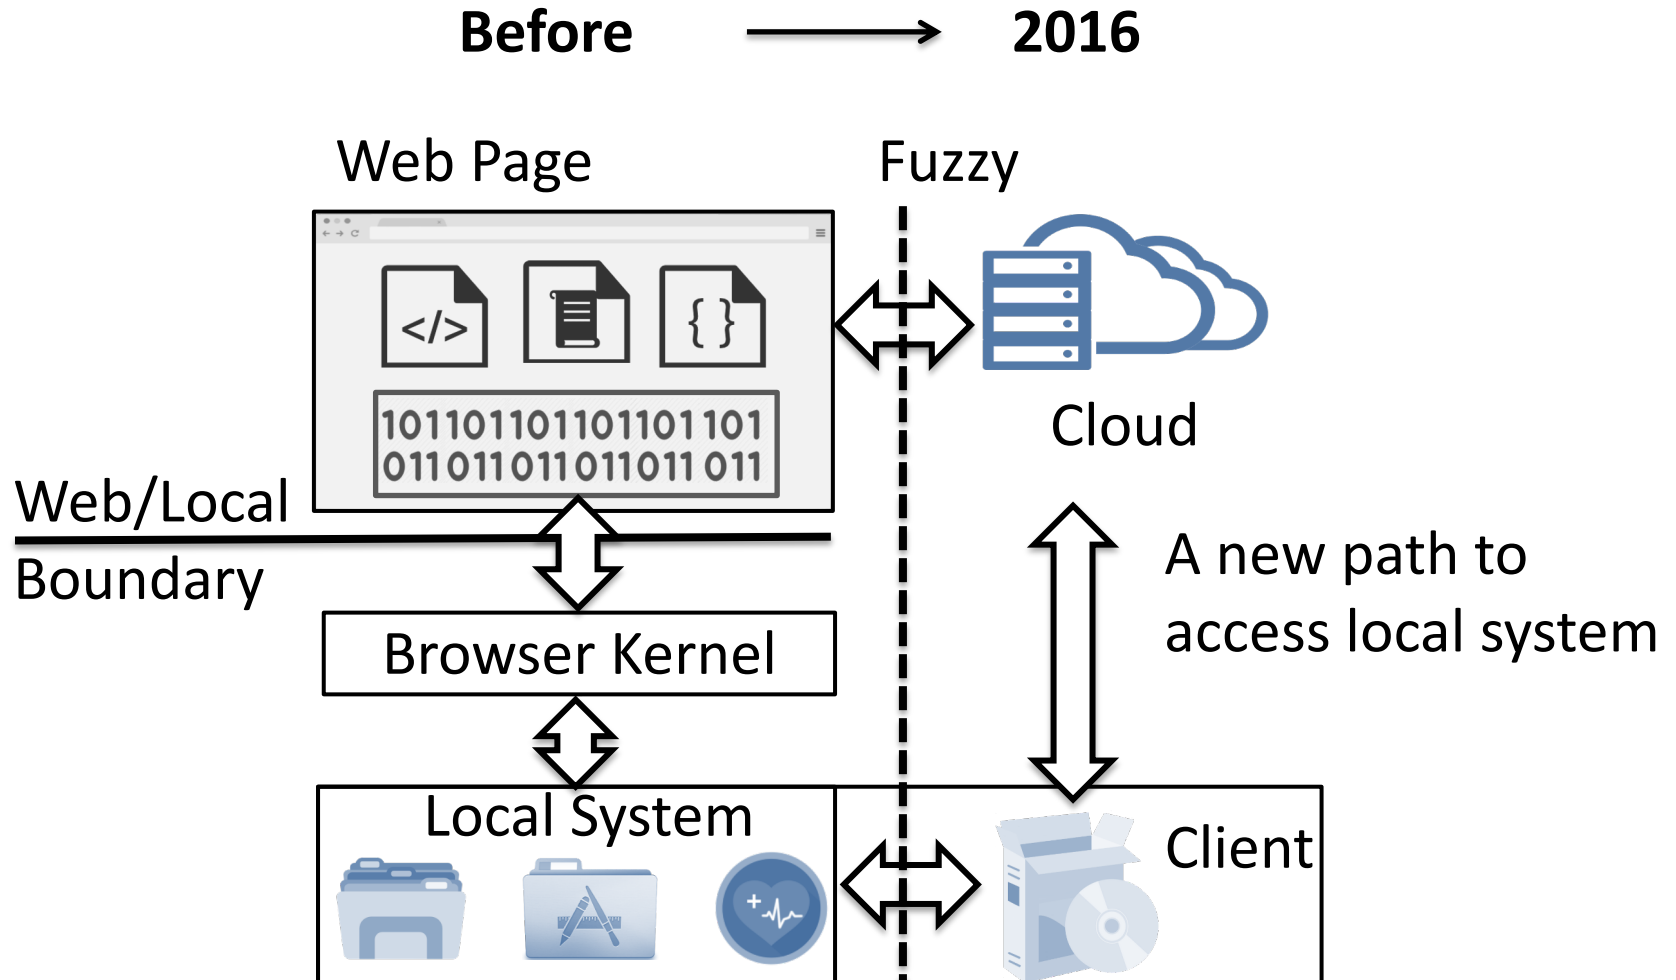

- Bypass in-memory protections using data-oriented attacks

## **Solutions**

- Imperfect existing solutions
- Our light-weight mitigation

# The Web/Local Boundary is Fuzzy

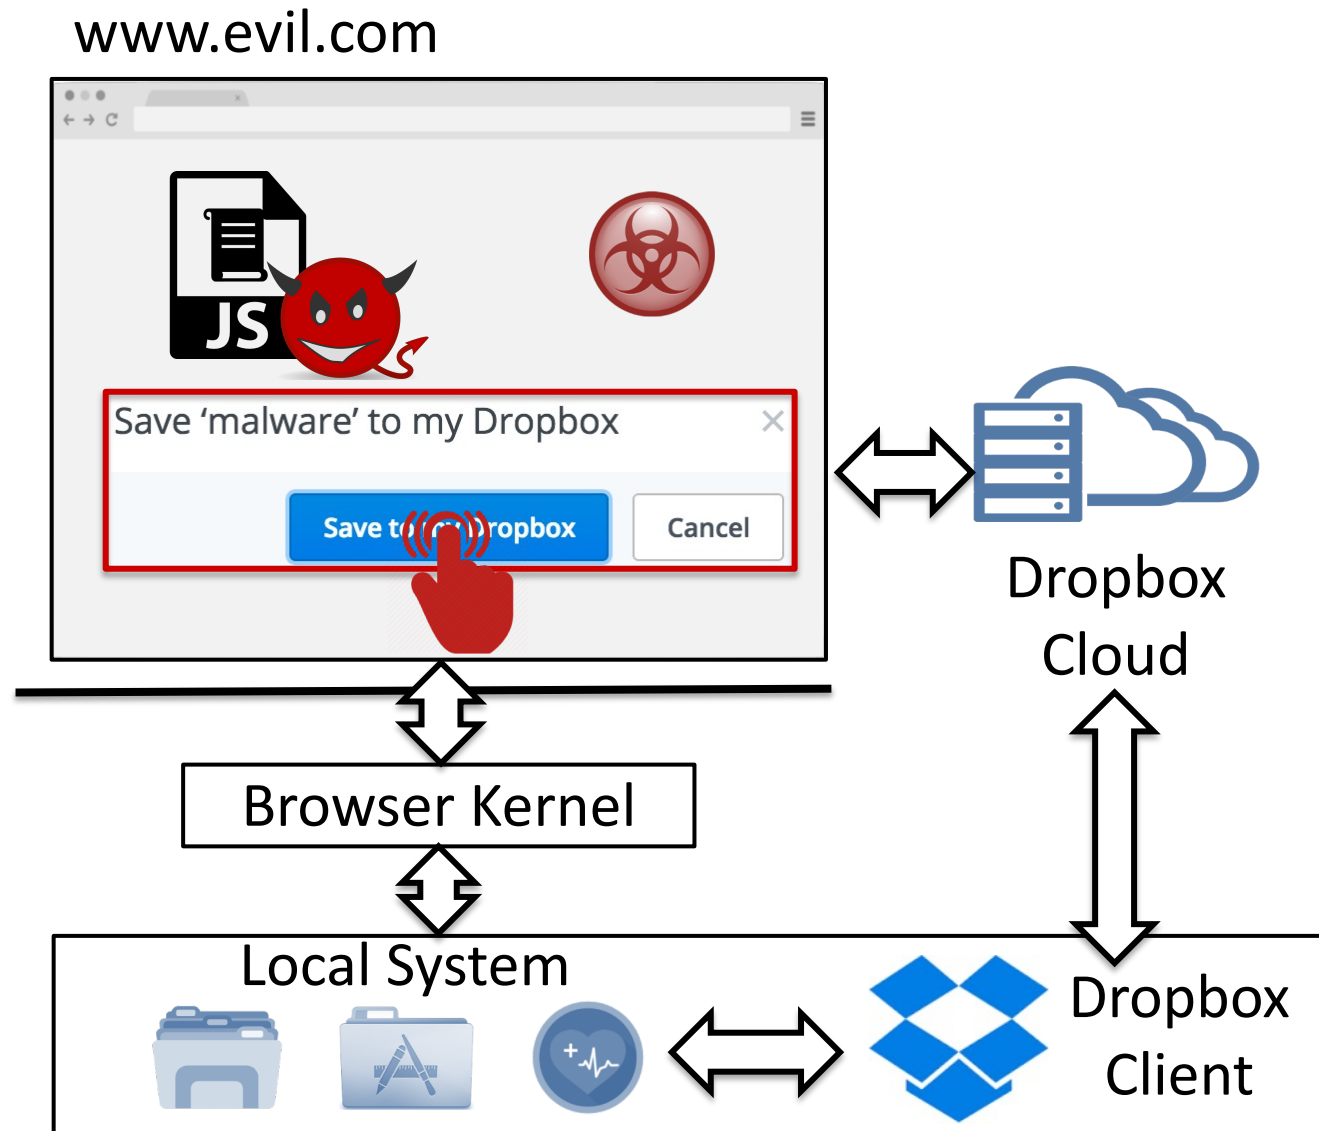

- Landscape changes --- Rise of the cloud services

# Attacks due to Fuzzy Web/Local Boundary

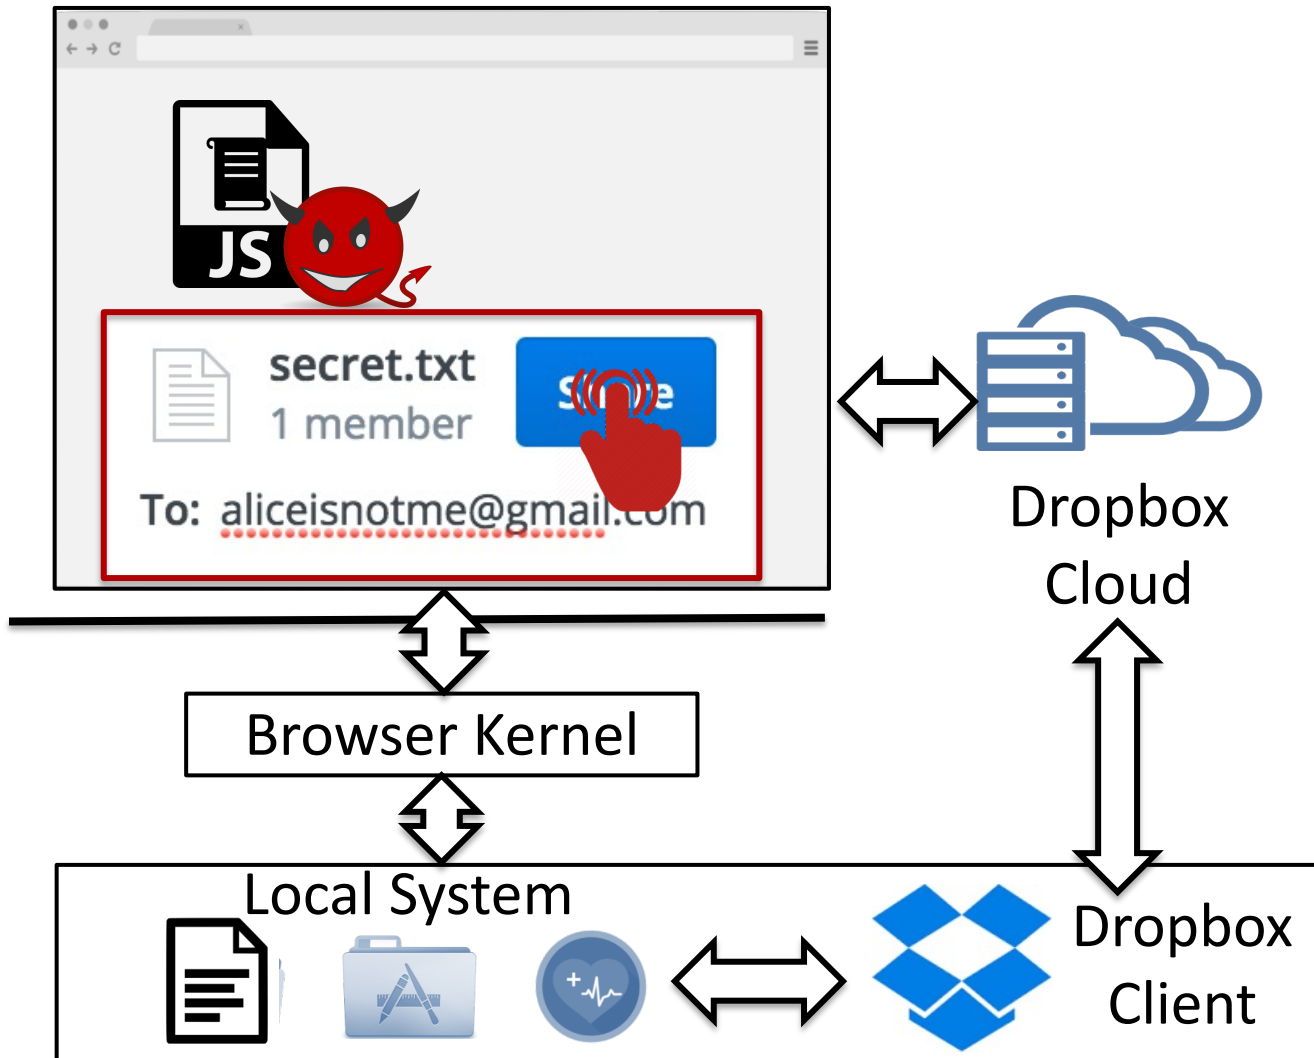

# Attack Example 1: Drop a Malware

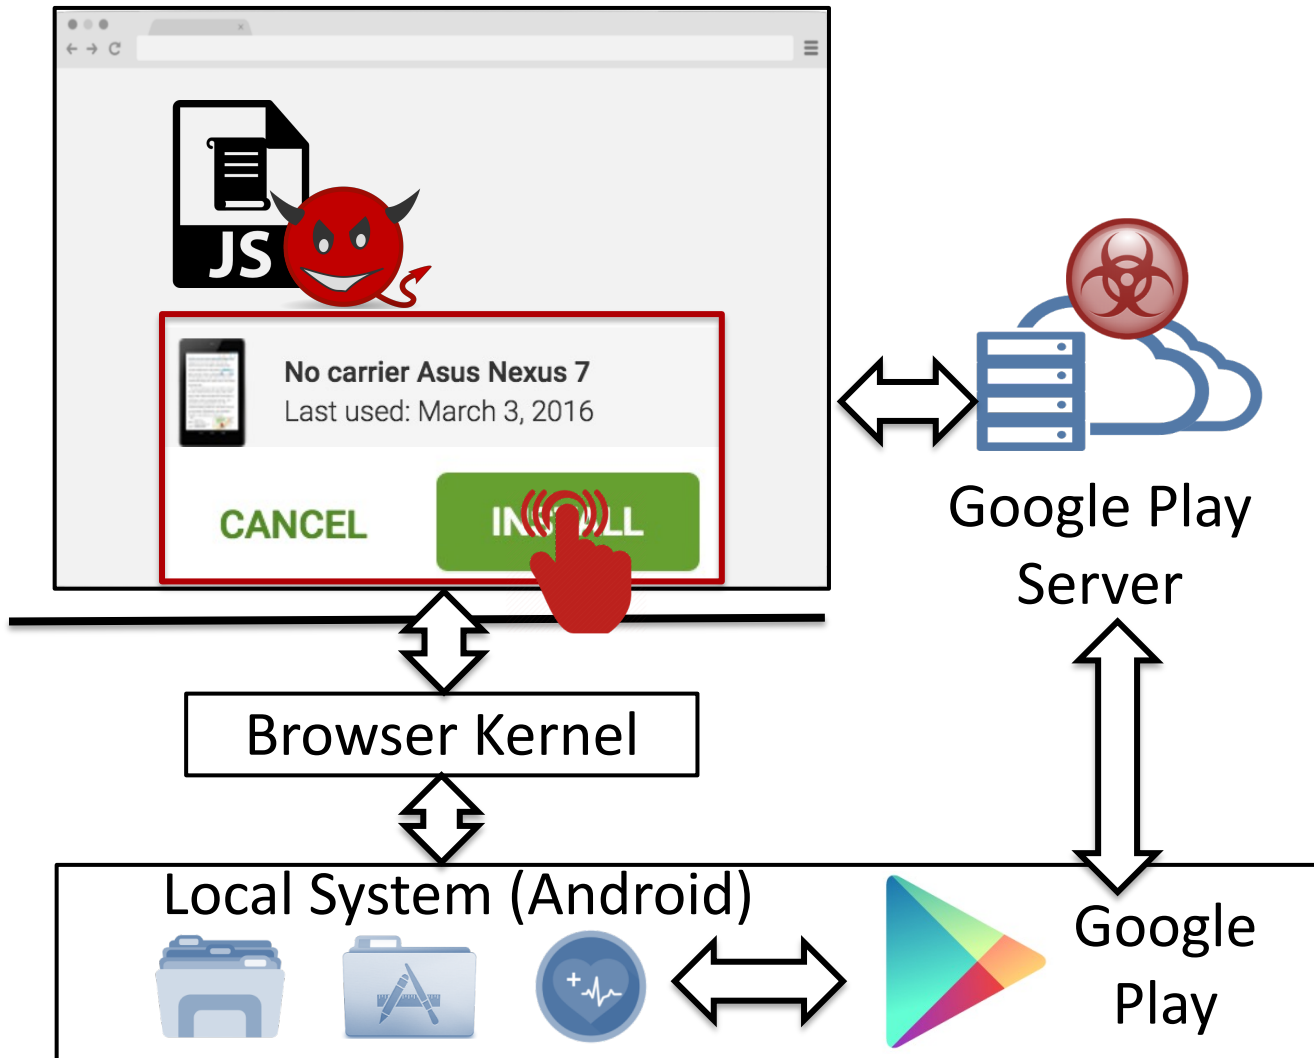

# Example 2: Steal a Local File

www.evil.com

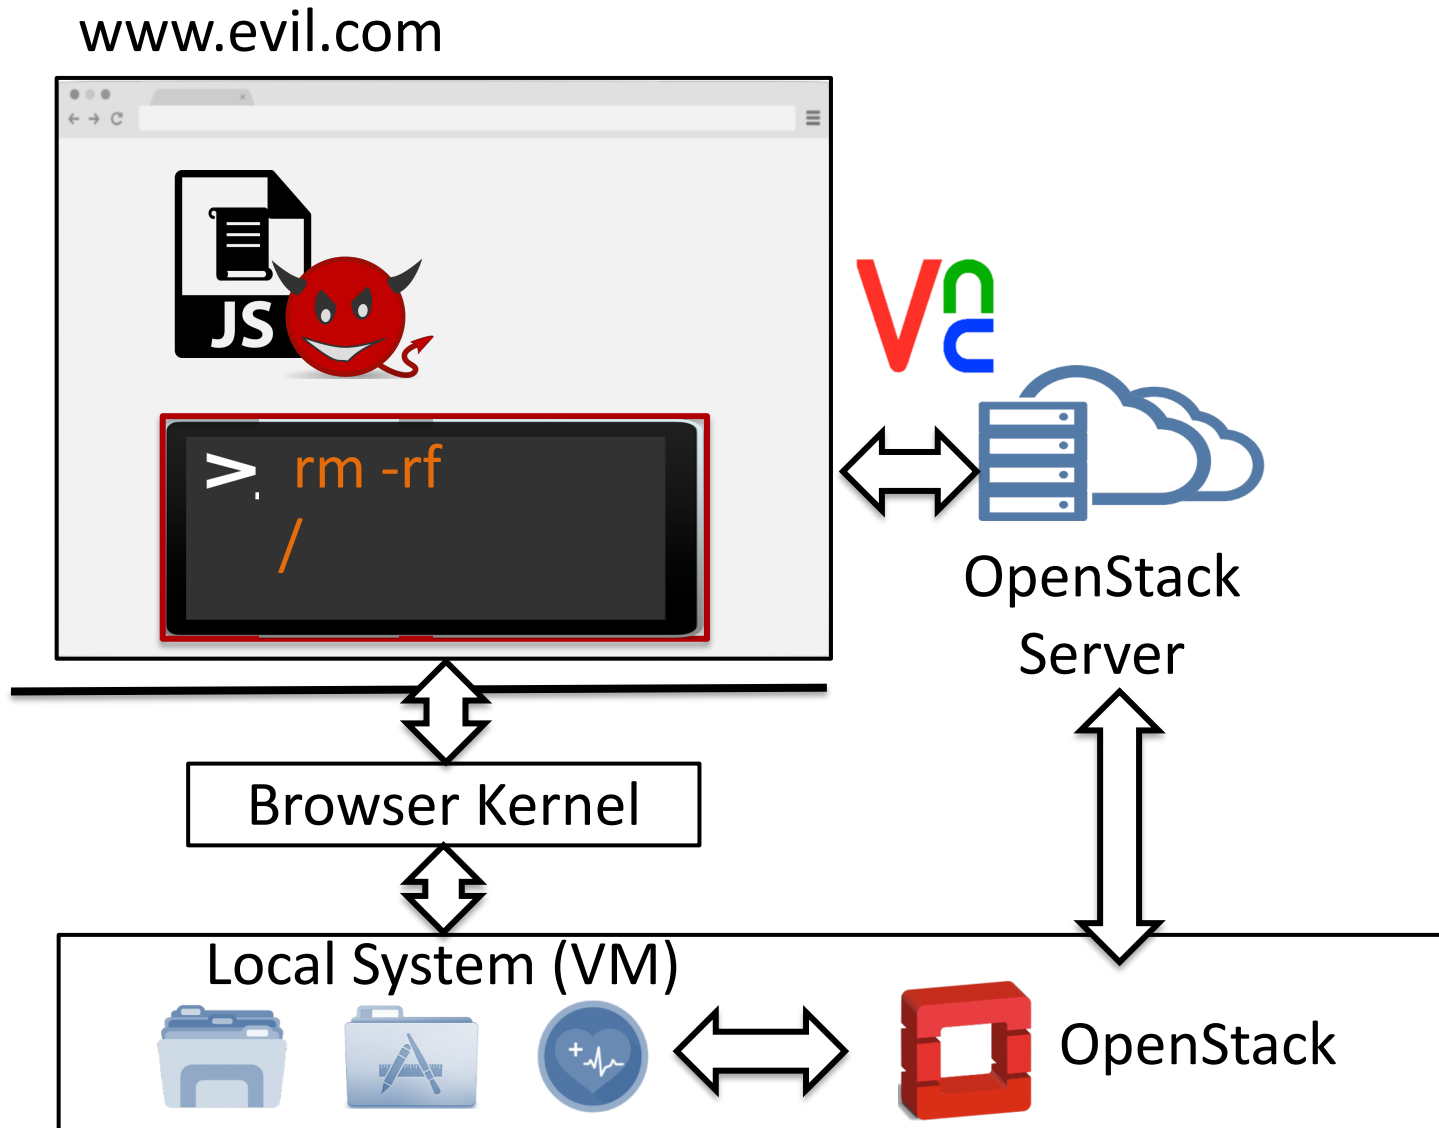

# Example 3: Install Malware

www.evil.com

# Example 4: Remote System Control

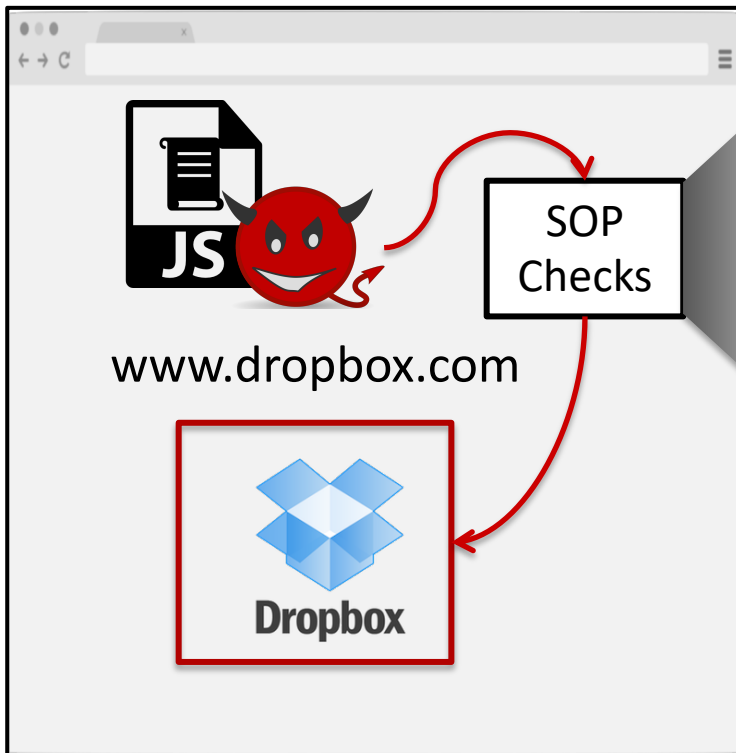

# But ... Chrome's Protections

- Same-Origin Policy (SOP)
- Control-Flow Integrity (CFI) *on the way*
- In-Memory Partitioning
- Internal Randomization

# SOP Enforcement in Chrome

www.evil.com

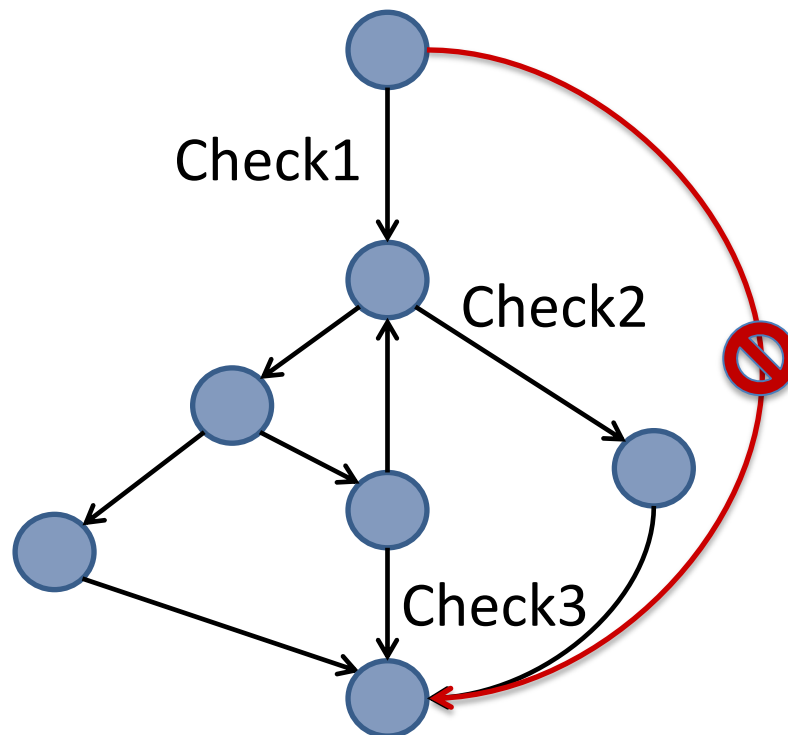

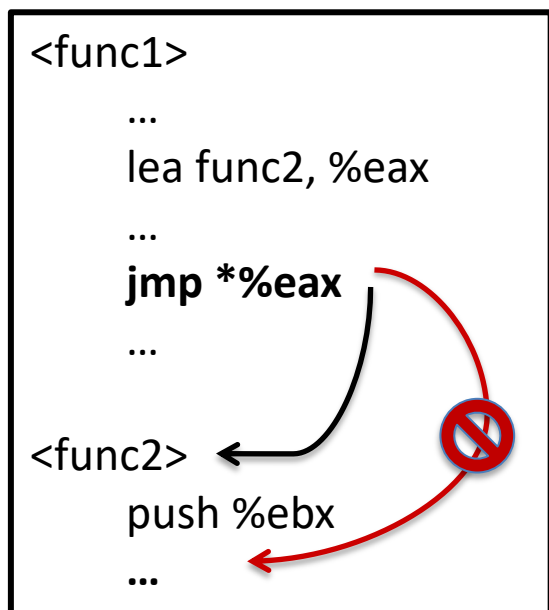

```
bool SecurityOrigin::canAccess() {  
    if (m_universalAccess)  
        return true;  
    if (this == other)  
        return true;  
    .....  
    return canAccess;}  
}
```

Various SOP checks for cross-origin read/write: `contentDocument`, `frames`, etc.

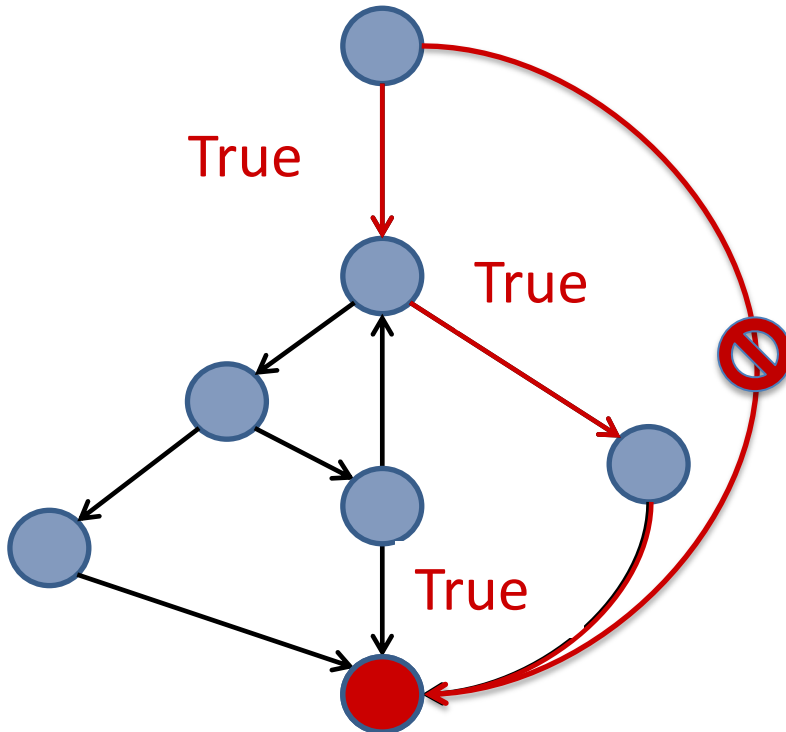

# Control-Flow Integrity

- CFI: control flows cannot be modified (on the way)

# Bypass SOP & CFI

- Corrupt critical data
  - Not modify control flow
  - Bypass SOP checks

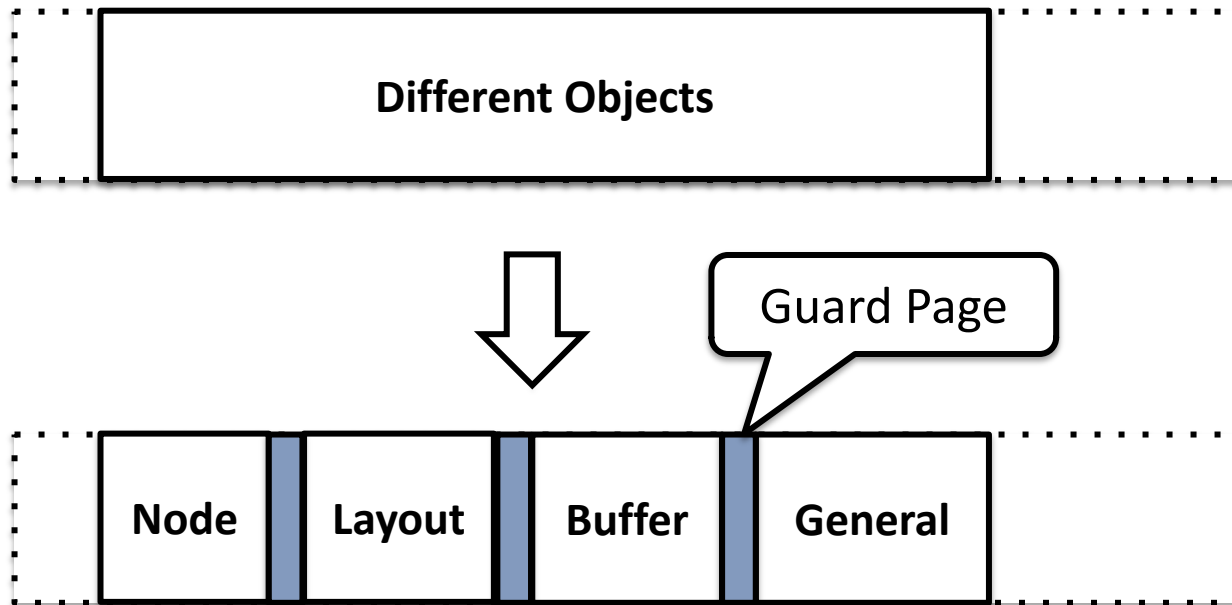

```
bool SecurityOrigin::canAccess() {  
    if (m_universalAccess)  
        return true;  
    if (this == other)  
        return true;  
    .....  
    return canAccess;  
}
```

When `m_universalAccess` is true, the check always passes

# In-Memory Partitioning

- Separate different types of objects in 4 partitions
- Surrounded by inaccessible guard pages

# Cross-Partition References to Bypass Partitioning

- Link objects in one partition to another
- Pervasive & often under the control of scripts
  - Dereference pointers to cross partition boundaries

# Partition-based Randomization

- Randomize the base address of each partition
- Guard pages cannot be read/written

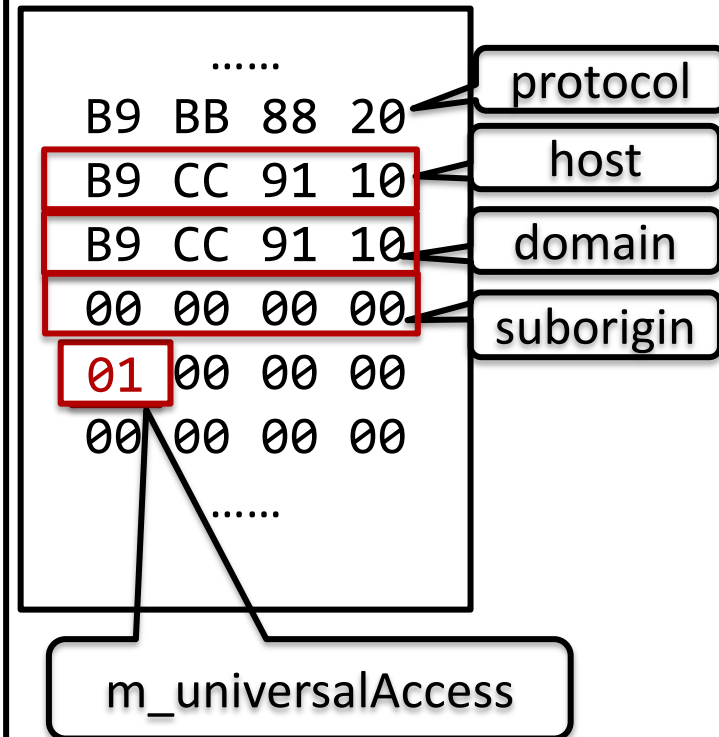

# Fingerprinting Technique to Bypass ASLR & Find Critical Data

- Special pattern for security monitor objects
- Linearly scan memory

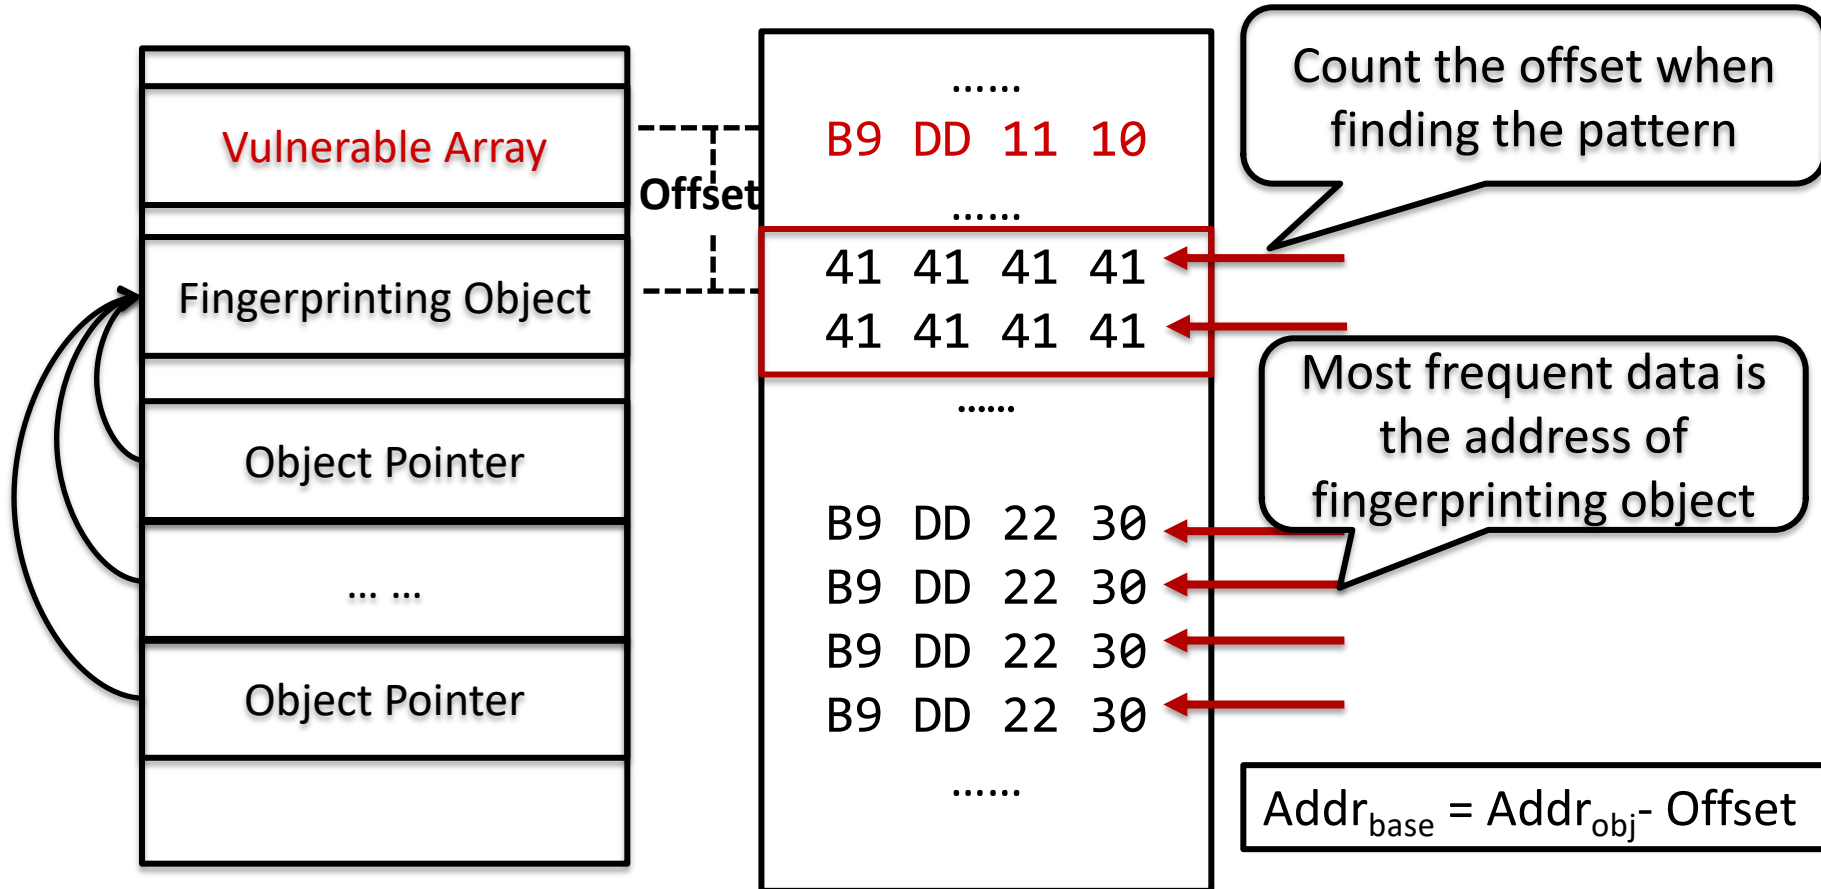

```
class PLATFORM_EXPORT SecurityOrigin
{
    .....
    String m_protocol;
    String m_host;
    String m_domain;
    String m_suboriginName;
    unsigned short m_port;
    bool m_isUnique;
    bool m_universalAccess;
    bool m_domainWasSetInDOM;
    bool m_canLoadLocalResources;
    bool m_blockLocalAccessFromLocalOrigin;
    bool m_needsDatabaseIdentifierQuirkForFiles;
};
```

Match the pattern

# Find the Address of Vulnerable Array

- Create a predictable “fingerprinting” object
- Linearly scan memory to find the object’s location

# Bypass SOP & In-Memory Protections

- SOP ✗  
Data-oriented attacks
- CFI ✗  
Data-oriented attacks
- In-memory partitioning ✗  
Cross-partition references
- Internal ASLR ✗  
Fingerprinting technique

Seems difficult to bypass

# Attack Implementation

- Work on proper memory error vulnerabilities
  - ✓ POC: CVE 2014-1705 heap overflow in V8 (Chrome 33)
- Over 10 SOP-related flags (Chrome 45)
- End-to-end attacks
  - ✓ Access files on the local system
    - Dropbox, Google Drive
  - ✓ Interact with local system
    - OpenStack, Google Play
  - ✓ Misuse system sensors
    - Fitbit, Runkeeper

Dropbox

Google Drive

Google play

openstack™

fitbit

# Protections against Web/Local Attacks

# Web Browser-Side Protection

- Memory safety
  - ✓ Huge code base, e.g., +5 million LOC for Chrome
- Software-based fault isolation (SFI)
  - ✓ Cross-partition references

# Light-Weight Mitigation

- Identify critical data
- ASLR to hide the address of critical data
  - ✓ Address of the critical data is not saved in user space
  - ✓ Average 3.8% overhead
- Raise the bar of Web/Local attacks

# Disclosure to Google

- Fine-grained process-based isolation
  - Chrome's Out-of-Process iframes
  - Performance overhead and massive refactoring

www.evil.com

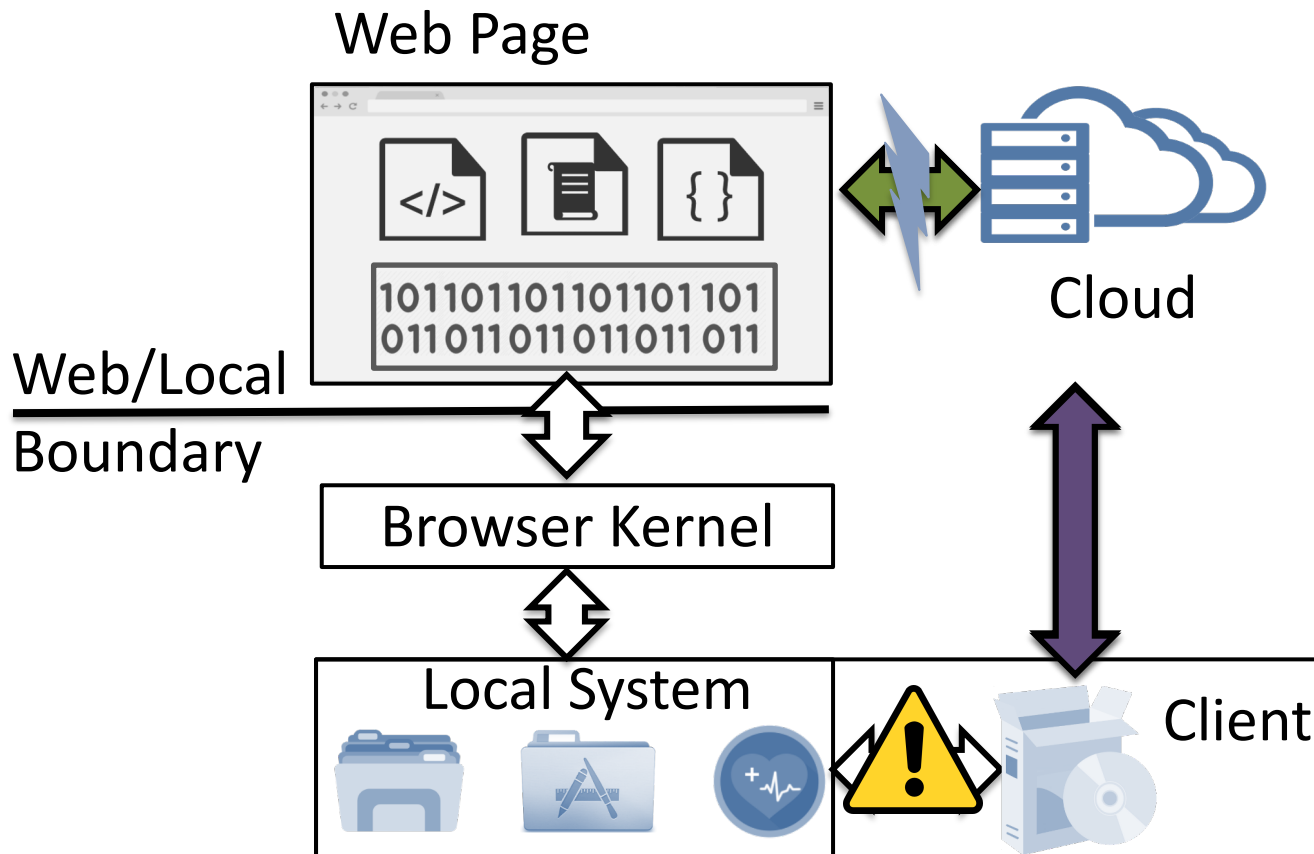

www.evil.com

# Cloud Service-Side Protection

- Distinguish requests of its site from client
- Restrict the privileges for the web interface
- Require the user's consent

# Conclusion

- Concrete Attacks on Web/Local Boundary
    - ✓ Access local files, system control
    - ✓ Using 1 bug in renderer process
  - Attack Details
    - ✓ Bypass in-memory protections
- Video at <https://youtu.be/flHaiQ4btok>
- POC at <https://github.com/jiayaoqijia/Web-Local-Attacks>
- Solutions
    - ✓ Imperfect existing solutions
    - ✓ Open to researchers

# Thanks

**Yaoqi Jia**
